

Type Casting Functions

Type casting in python allows programmers to convert variables or data from one data type to another

→ Type casting in python can be very useful in dealing with large data sets where data is present in different data types

In python we have two types of type conversion

- ① Implicit type conversion
- ② Explicit type conversion

Implicit type conversion

Python automatically converting one type of data into another type

- ③ Explicit type conversion

→ By using type casting function (or eval()) we can convert one type of data into another type

Ex:- `t = (10, 20.50, 'hi')` (Implicit)

`a, b, c = t`

`a = 10`

`b = 20.50`

`c = hi`

Ex:- `a = 10`
`type(a)` (Explicit)
