

Python constant

In Python a constant is a value that should not change during the execution of a program

Note:-

Python does not have built in constant types like some other languages

(eg final in Java or const in C++)

→ But by naming convention, constants are written in uppercase letters

How to define a constant in Python

Python does not restrict variable value, so we follow upper case naming convention to define constants

→ constants are of case

Ex:-

PI = 3.141459

By Convention

→ constants are written in all caps

→ defined at the top of the file

→ not supposed to be changed by programmers
