

Python Keywords Concept

- Keyword is nothing but a predefined reserved word
- every keyword having its own behaviour
- we cannot change the keyword behaviour
- If we are trying to change the keyword behaviour then it will return syntax error
- In Python we have 35 keywords
- all keywords are available in a predefined "keyword" module
- by using "import keyword" we can import keyword module
- by using `keyword.kwlist` argument we can display all available keywords from a keyword module

`import keyword`
`keyword.kwlist` } we can see

- There are three capitalized keywords
- 1) True
- 2) False
- 3) None

Note: If we know to find the length of
Keyword
`len(keyword.kwlist)`

Keywords cannot be used as identifiers (variables names, function names, class names etc)

Because they are used to define the syntax and structure of Python language

If you try to use keywords as a userdefined names then throws syntax error.
