

Python file handling

Python file concepts-

- All Programming Language Program memory allocation takes place in a RAM area at the time of execution of the Program
- RAM is volatile memory so that after execution of Program the memory is going to be deallocated
- Any Programming Language Programs are good at processing ~~time~~ data but they can not store data in permanent manner
- If the data is stored in permanent manner, we can use whenever we want
- we can store the data in permanent manner by using File

File is a name location on disk which is used to store the related data in permanent manner in the hard disk

- By using Python script we can manipulate the data of given file
(we can create, update, delete)

* If we want to work with files concept in Python then we need to open the file by using open() function

IMP Point

- * At the time of opening the file we have to specify the file modes
- * Mode of the file indicates what purpose we are going to open the file

Syntax :- `open ( "filename File-Name" , "mode-of-File" )`

for Example :- `fileobject = open('demo.txt', 'r')`
`fileobjects.close()`

with `open ('demo.txt', 'r')` as file object :-

Seek (offset, whence) method

- The seek() method in Python file handling is used to move the file cursor to a specific position of a file.
- This allows reading or writing from a particular location in the file instead of from the beginning or end.
- It is accepting two arguments as a input they are
 - offset : how many bytes to move (forward, backward)
 - whence :- Optional, default is 0
- 0 → From start of file
- 1 → From current position
- 2 → From end of file

Methods

File object = open('FileName', "r")

File object . read()

File object . readline()

File object . readlines()

File object . tell()

File object . seek(0, 0)

File object . seek(0, 1)

File object . seek(0, 2)

File object . close()

fileobject.name

fileobject.mode

fileobject.closed

Writing Data into Files

```
fileobject = open('FileName', 'w')
```

```
fileobject.write("...")
```

```
fileobject.writelines(['line1', 'line2', ...]) # concatenate  
as a single
```

```
fileobject.writelines(['line1\n', 'line2\n', ...])
```

```
---  
---  
---
```

```
fileobject.close()
```

```
with open('FileName', 'w') as fileobject:
```

```
    fileobject.write(data)
```

```
---  
---  
---
```

```
fileobject.close()
```

```
---  
---  
---
```
